

Economic benefits of nature-based solutions: instruments to support decision-making

[Sien Kok](#) resource economist Deltares & Wageningen University

Sien.kok@Deltares.nl

9-11-2021

Introduction

- NBS = panacea?
- Increasing attention + flood of reports about their economic value
 - Dasgupta review (2021): value nature should be at heart of economics
 - WWF living planet (2018): nature's value estimated US\$125 trillion
 - IISD (2021): investment gap development = USD 489 bln w/ grey infra; only 50,7% with NBS
- But do NBS always make economic sense and (how) can we substantiate that?
- This presentation:
 - What is 'economic sense?' > depends on the context
 - Tools to support valuation
 - Value of NBS benefits on water quality

NBS: cost-effective?

- Cost effectiveness: how costly a measure is in relation to a single goal
- When to use?
 - Identify least-cost alternative to achieve single goal (cost minimization)
 - Quite common
- How is it calculated?
 - Amount of 'effect' expected with measure
 - Costs per unit effect
- Example tool: toolbox resilient cities

cm water
table
lowered

% soil
moisture
increased

NBS: cost-effective?

The screenshot displays the 'Climate Resilient Cities Toolbox' interface. On the left, under 'Applied Measures', the 'Bioswale (with drainage)' measure is selected and active. The central map shows a street layout with a yellow line indicating the bioswale's location. On the right, the 'Results' panel is visible, containing two sections: 'Climate' and 'Cost'. The 'Climate' section lists metrics such as storage capacity, groundwater recharge, and evapotranspiration. The 'Cost' section lists construction and maintenance expenses. Two red circles highlight the 'Storage capacity (m³)' and 'Construction (€)' values.

Category	Metric	Value
Climate	Storage capacity (m ³)	43,5
	Groundwater recharge (mm/year)	1,25
	Evapotranspiration (mm/year)	-0,01
	Heat reduction (°C)	0
	Cool areas (number)	0
	Return Time Factor (-)	1,27
Cost	Construction (€)	9.322
	Maintenance (€/year)	93,22

NBS: cost-effective?

- Cost effectiveness: how costly a measure is in relation to a single goal
- How is it calculated?
 - Amount of 'effect' expected with measure
 - Costs per unit effect
- When to use?
 - Identify least-cost alternative to achieve single goal (cost minimization)
 - Quite common
- Example tool: toolbox resilient cities
- CE of NBS affected by ...
- But: key benefit of NBS is that they are multifunctional.

Local physical setting

Required performance level

Already infrastructure present?

Innovation > higher risk premiums in costs

NBS: the economic rationale for investment

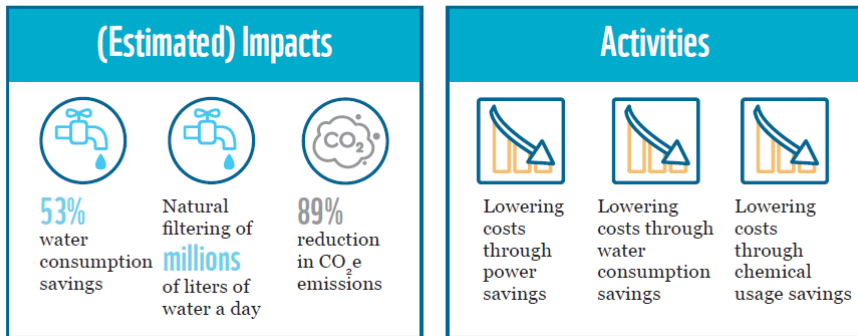

- What: Cost-benefit analysis
- Investment costs are compared against welfare effects, in monetary terms (€).
- Socio- economic rationale for investment
 - Benefit-cost ratio > 1
 - Balance = positive
- Often mandatory for public investments of certain scale
- Wide array of guidelines and databases to support; increasing number for NBS
- Quick-scan tools
 - CNT Value calculator
 - BEST (sustainable urban drainage)
 - TEEB City
 - **Nature Value Explorer**

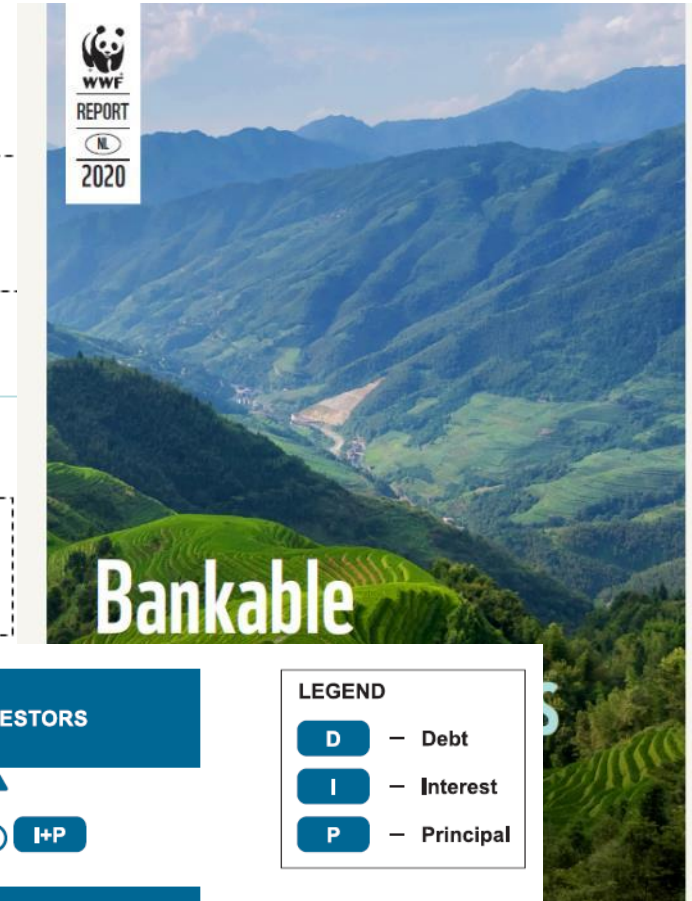

NBS: a business case?

- Business case = private/ cash flow perspective
- Private actor:
 - Revenue (cash flow) > costs
 - Cost-effective solution
- Example: wetland project to increase water quality

7. INGOLDISTHORPE WETLAND

Deltares

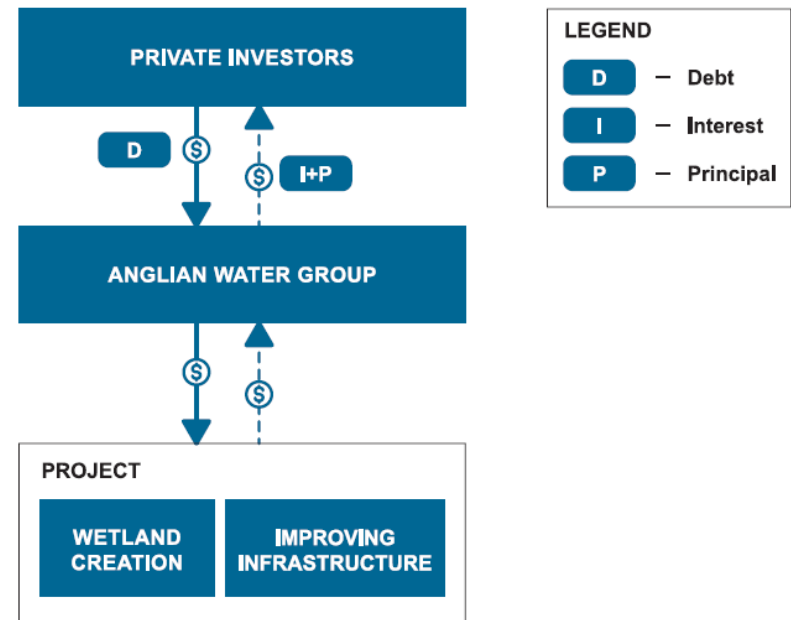

Public good/
service: public
investment

Revenues < cost

No rationale for
investment; no
initiators

Figure 15:
Anglian Water issued a first ever Class A £250 million green bond in the UK water sector with a tenor of 8 years. £500 thousand was used to fund the Ingoldisthorpe Wetland project.

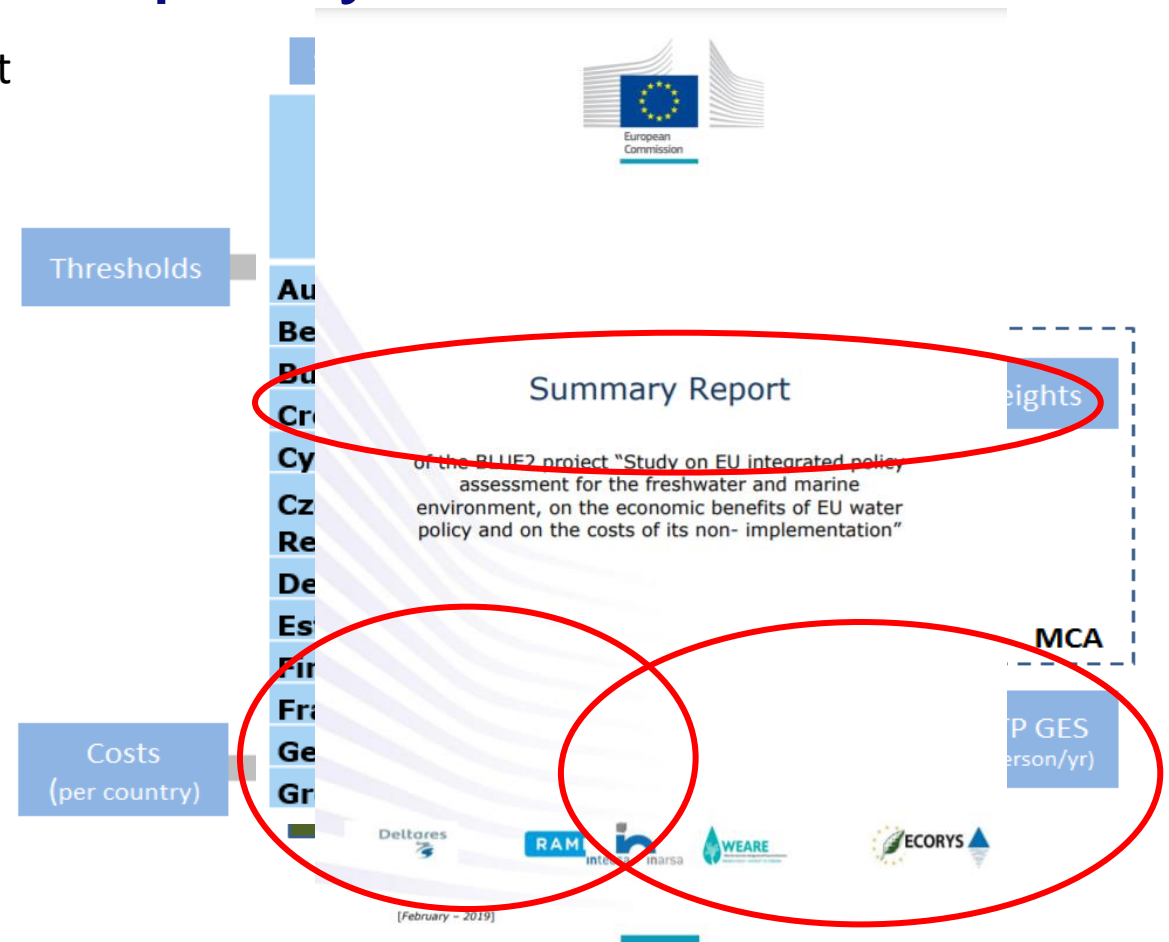

ness

Economic valuation of water quality

- EC Blue2 study (2017-2018): socio-economic assessment of policies for water quality
- Approach # 1 Valuation methods based on MSFD/WFD indicators:
 - Cost-effectiveness
 - Goal: achieve good status (UWWT not included)
- Approach # 2 Valuation methods based on changes in ecosystem services:
 - Cost-benefit analysis (based on TEV/Ecosystem service accounting)
 - E.g. Contingent valuation: Willingness to pay

Other options: E.g. water purification > cost savings in drinking water production, fish production (# fish * price), health impacts (# less disease * health care costs), recreation (travel time)

Evidence on impact NBS on water quality

- Analysis of EU funded NBS projects on water quality & waterbody conditions (2020)
- Some highlights:
 - Point sources (e.g. combined sewer flows) > integration of NBS like constructed wetlands, green roofs etc can lead to cost-savings reduced stormwater flow, decreased CSO spills
 - Urban diffuse pollution control: NBS only viable solutions (green roofs, bioswales, attenuation ponds)
 - Many case studies with positive benefit-outcome on water quality & other grounds

Key Take-aways

- NBS or hybrid infrastructure can be cost-effective;
- But economic value especially clear in broader CBA > NBS = multifunctional;
- Mounting evidence on economic rationale, including for water quality;
- But at the same time difficult, due to lack of data & limited monitoring;
- next up: H2020 Green deal Merlin project (2021-2025)
